## Triple DC-DC Boost Converter for AMOLED

### **General Description**

The RT4720AC is a triple channels DC-DC converter which is designed to provide the power of AMOLED. It integrates step up DC-DC and an inverting converter to provide the positive and negative output voltage required by AMOLED.

For the portable application, board space and efficiency are always major concerns. The high switching frequency of the RT4720AC allows the use of low inductance inductor to save the board space. It provides dual positive output voltage, one is a fixed 5.8V or 7.7V output voltage by SEL pin and the other positive output is fixed 4.6V. For the negative output voltage, it can be programmed by external MCU through single wire (SWIRE pin). The output voltage range of negative output voltage is -1.4V to -5.4V. The RT4720AC has OTP, SCP, UVLO and over-current protections. The RT4720AC is available in a WQFN-16L 3x3 package to achieve saving PCB space.

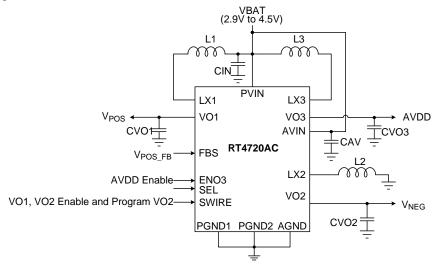

## Applications

- Cellular Phones
- Digital Cameras
- PDAs and Smart Phones
- Probable Instrument

### Features

- Boost Converter to Supply Positive AVDD Voltage Fixed 5.8V or 7.7V
- Boost Converter to Supply AMOLED Positive Voltage 4.6V
- Inverter Converter to Supply AMOLED Negative Voltage From –1.4V to –5.4V
- Maximum Output Current up to 300mA for AMOLED Positive & Negative Power Supply
- Maximum Output Current up to 50mA for Fixed 5.8V or 7.7V AVDD Output Voltage
- Typical Peak Efficiency : 90% (40mA to 150mA)
- PWM Mode @ 1.5MHz Switching Frequency
- High Output Voltage Accuracy
- Excellent Line and Load Transient
- Excellent Line and Load Regulation
- Programmable Negative Voltage by SWIRE Pin
- Fast Outputs Discharge Function
- Low Quiescent Current < 1µA in Shutdown Mode
- Internal Soft-Start to limit Inrush Current
- Over-Temperature Protection (OTP)
- Over-Current Protection (OCP)
- Short Circuit Protection (SCP)

### **Simplified Application Circuit**

## **Ordering Information**

### RT4720AC

Package Type QW : WQFN-16L 3x3 (W-Type)

Lead Plating System
 G : Green (Halogen Free and Pb Free)

Note :

Richtek products are :

RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.

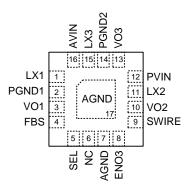

Suitable for use in SnPb or Pb-free soldering processes.

## **Marking Information**

LL=YM DNN LL= : Product Code YMDNN : Date Code

## **Pin Configuration**

(TOP VIEW)

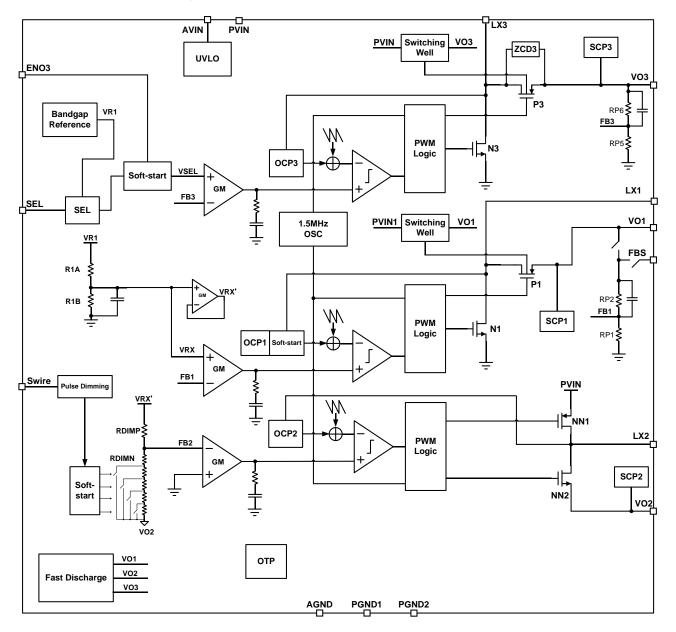

WQFN-16L 3x3

Pin No.	Pin Name	Pin Function
1	LX1	1 <sup>st</sup> boost converter switching node.
2	PGND1	Power ground.
3	VO1	1 <sup>st</sup> boost converter output.
4	FBS	1 <sup>st</sup> boost converter output feedback sense.
5	SEL	2 <sup>nd</sup> boost converter output voltage select pin. High = 5.8V, Low = 7.7V output, default floating.
6	NC	No connected.
7, 17 (Exposed Pad)	AGND	Signal ground. The exposed pad must be soldered to a large PCB and connected to AGND for maximum power dissipation.
8	ENO3	2 <sup>nd</sup> boost enable/disable pin.
9	SWIRE	VPOS, VNEG control pin (enable/disable pin).
10	VO2	Buck/Boost converter output (negative voltage).
11	LX2	Buck/Boost converter switching mode.
12	PVIN	Power input voltage.
13	VO3	2 <sup>nd</sup> boost converter output.
14	PGND2	Power ground.
15	LX3	2 <sup>nd</sup> boost converter switching node.
16	AVIN	Analog input voltage.

### **Functional Block Diagram**

### Operation

The RT4720AC is a triple channels DC-DC converter which is designed to provide the power of AMOLED that can support the input voltage range from 2.9V to 4.5V. The VO1 & VO2 output current can be up to 300mA, and the VO3 output current can be up to 50mA. The RT4720AC uses current mode architecture for the purpose of high efficiency and high transient response. The VO1 positive output voltage is produced from the DC-DC Boost converter and is set at a typical value of 4.6V. When the SWIRE goes high, the positive output

voltage will be enabled with an internal soft-start

process. The VO2 negative output voltage is produced from the DC-DC buck-boost converter and the negative output voltage range is -1.4V to -5.4V. It can be programmed by external MCU through single wire (SWIRE pin). The VO3 positive output voltage is produced from the DC-DC Boost converter and is set at a fixed 7.7V or 5.8V by SEL pin. When SWIRE goes high and VO1 soft-start had finished already, negative output voltage VO2 will be enabled with an internal soft-start process.

Bit (Pulse)	VO2 (V)	Bit (Pulse)	VO2 (V)

- **Note 1.** Stresses beyond those listed "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
- Note 2.  $\theta_{JA}$  is measured under natural convection (still air) at  $T_A = 25^{\circ}C$  with the component mounted on a high effective-thermal-conductivity four-layer test board on a JEDEC 51-7 thermal measurement standard.  $\theta_{JC}$  is measured at the exposed pad of the package.
- Note 3. Devices are ESD sensitive. Handling precaution recommended.
- Note 4. The device is not guaranteed to function outside its operating conditions.

### **Application Information**

The RT4720AC is a triple channels DC-DC converter, which integrates dual step up converter and an inverting converter to provide the positive and negative output voltage required by AMOLED. The RT4720AC protection function includes Over-Temperature Protection (OTP), Over-Current Protection (OCP) and Short Circuit Protection (SCP), also it has Pulse Skipping Mode (PSM) to provide high efficiency during light load.

### Soft-Start

The RT4720AC use an internal soft-start feature to avoid high inrush currents during step-up.

### **Fast Discharge Function**

All outputs voltage use an embedded discharge function to discharge the remaining output to 0V rapidly, preventing phenomena such as residual image on the display during shutdown.

### **Over-Temperature Protection (OTP)**

The RT4720AC includes an Over-Temperature Protection (OTP) feature to prevent excessive power dissipation from overheating the device. The OTP will shut down switching operation when junction temperature exceeds 140°C. Once the junction temperature cools down by approximately 15°C, the converter resumes operation.

To maintain continuous operation, prevent the maximum junction temperature from rising above 125°C.

### **Over-Current Protection (OCP)**

The RT4720AC includes a current sensing circuitry which monitors the inductor current during each ON period. If the current value becomes greater than the current limit, the switch that pertains to inductor charging will turn off, forcing the inductor to leave charging stage and enter discharge stage.

### **Short Circuit Protection (SCP)**

The RT4720AC has an advanced short circuit protection mechanism which prevents damage to the device from unexpected applications. When the output voltage becomes lower than about 90%, over 1ms the

device enters shutdown mode. VO3 can only re-start normal operation after triggering the ENO3 pin and VO1, VO2 can only re-start normal operation after triggering the SWIRE pin.

### Under-Voltage Lockout (UVLO)

To prevent abnormal operation of the IC in low voltage condition, an under-voltage lockout is included, which shuts down the device at voltages lower than 2.2V. All functions will be turned off in this state.

### Input Capacitor Selection

Each channel input ceramic capacitors with  $10\mu$ F capacitance are suggested for the RT4720AC applications. However, to achieve best performance with the RT4720AC, larger capacitance can be used. For better voltage filtering, select ceramic capacitors with low ESR, X5R and X7R types which are suitable because of their wider voltage and temperature ranges.

### **Boost Inductor Selection**

The inductance depends on the maximum input current. As a general rule, the inductor ripple current range is 20% to 40% of the maximum input current. If 40% is selected as an example, the inductor ripple current can be calculated according to the following equations :

$$I_{IN(MAX)} = \frac{V_{OUT} \times I_{OUT(MAX)}}{\eta \times V_{IN}}$$
$$\Delta I_{L} = 0.4 \times I_{IN(MAX)}$$

where  $\eta$  is the efficiency of the converter,  $I_{\text{IN(MAX)}}$  is the maximum input current, and  $\Delta I_{\text{L}}$  is the inductor ripple current. The input peak current can then be obtained by adding the maximum input current with half of the inductor ripple current as shown in the following equation :

IPEAK =  $1.2 \times IIN(MAX)$ 

Note that the saturated current of the inductor must be greater than IPEAK.

The inductance can eventually be determined according to the following equation :

$$L = \frac{\eta \times (V_{IN})^2 \times (V_{OUT} - V_{IN})}{0.4 \times (V_{OUT})^2 \times I_{OUT(MAX)} \times f_{OSC}}$$

where fosc is the switching frequency. For better system performance, a shielded inductor is preferred to avoid EMI problems.

#### **Boost Output Capacitor Selection**

The output ripple voltage is an important index for estimating chip performance. This portion consists of two parts. One is the product of the inductor peak current with the ESR of the output capacitor, while the other part is formed by the charging and discharging process of the output capacitor. As shown in Figure 1,  $\Delta V_{OUT1}$  can be evaluated based on the ideal energy equalization. According to the definition of Q, the Q value can be calculated as the following equation :

$$Q = \frac{1}{2} \times \left[ \left( I_{IN} + \frac{1}{2} \Delta I_L - I_{OUT} \right) + \left( I_{IN} - \frac{1}{2} \Delta I_L - I_{OUT} \right) \right]$$
$$\times \frac{V_{IN}}{V_{OUT}} \times \frac{1}{f_{OSC}} = C_{OUT} \times V_{OUT1}$$

where fosc is the switching frequency and  $\Delta I_L$  is the inductor ripple current. Bring COUT to the left side to estimate the value of  $\Delta V_{OUT1}$  according to the following equation :

$$\Delta V_{OUT1} = \Delta V_{ESR} + \frac{D \times I_{OUT}}{\eta \times C_{OUT} \times f_{OSC}}$$

where  $\Delta V_{ESR} = \Delta I_C \times R_C ESR = I_{PEAK} \times R_C ESR$ 

The output capacitor,  $C_{OUT}$ , should be selected accordingly.

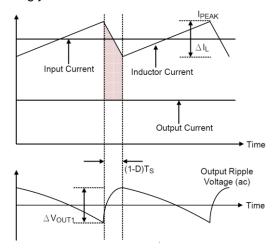

Figure 1. The Output Ripple Voltage without the Contribution of ESR

### **AVDD Output Voltage Setting**

The AVDD boost output voltage VO3 is fixed 7.7V or 5.8V output voltage by SEL pin. When SEL pin is set to high, the output voltage is 5.8V or otherwise SEL pin is set to low, the output voltage is changed to 7.7V.

#### **Buck-boost Converter Inductor Selection**

The first step in the design procedure is to verify whether the maximum possible output current of the buck-boost converter supports the specific application requirements. To simply the calculation, the fastest approach is to estimate converter efficiency by taking the efficiency numbers from provided efficiency curves or to use a worst case assumption for the expected efficiency, e.g., 80%. The calculation must be performed for the minimum assumed input voltage where the peak switch current is the highest. The inductor has an internal switch to be able to handle this current.

Converter Duty Cycle :

$$D = \frac{-V_{OUT}}{V_{IN} \times \eta - V_{OUT}}$$

Maximum output current :

$$I_{OUT} = \left(I_{PEAK} - \frac{V_{IN} \times D}{2 \times f_{OSC} \times L}\right) \times (1-D)$$

Inductor peak current :

$$I_{\text{PEAK}} = \frac{I_{\text{OUT}}}{1 - D} + \frac{V_{\text{IN}} \times D}{2 \times f_{\text{OSC}} \times L}$$

As for inductance, we are going to derive the transition point, where the converter toggles from CCM to DCM. We need to define the point at which the inductor current ripple touches zero, and as the power switch SW is immediately reactivated, the current ramps up again. Figure 2 portrays the input current activity of the buck-boost converter.

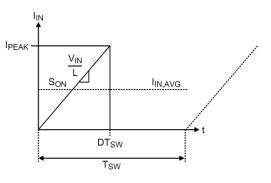

Figure 2. The Buck-Boost Input Signature in BCM

The inductance can eventually be determined according to the following equation :

$$L_{critical} = \frac{\left|V_{OUT}\right| \times \eta}{2 \times f_{OSC} \times I_{OUT}} \times \left(\frac{V_{IN}}{V_{IN} + \left|V_{OUT}\right|}\right)^2$$

### **Buck-Boost Converter Output Capacitor Selection**

For the best output voltage filtering, low ESR ceramic capacitors are recommended. One  $22\mu$ F output capacitors with sufficient voltage ratings in parallel are adequate for most applications. Additional capacitors can be added to improve load transient response.

To calculate the output voltage ripple, the following equations can be used :

$$\Delta V = \frac{D \times |V_{OUT}|}{f_{OSC} \times R_{LOAD} \times C_{OUT}} + \Delta V_{ESR}$$
where
$$\Delta V_{ESR} = \Delta I_C \times R_{C_{ESR}} = I_{PEAK} \times R_{C_{ESR}}$$

 $\Delta VESR$  can be neglected in many cases since ceramic capacitors provides very low ESR.

### **Negative Output Voltage Setting**

Buck-boost converter is implementing a pulse dimming method to control the output voltage (VO2) and its value is from -1.4V to -5.4V in 0.1V increments. User can control VO2 by SWIRE command. See SWIRE command section for details on how to adjust the output voltage.

### **Thermal Considerations**

The junction temperature should never exceed the absolute maximum junction temperature T<sub>J</sub>(MAX), listed under Absolute Maximum Ratings, to avoid permanent damage to the device. The maximum allowable power dissipation depends on the thermal resistance of the IC package, the PCB layout, the rate of surrounding airflow, and the difference between the junction and ambient temperatures. The maximum power dissipation can be calculated using the following formula :

 $\mathsf{PD}(\mathsf{MAX}) = (\mathsf{TJ}(\mathsf{MAX}) - \mathsf{TA}) / \theta \mathsf{JA}$ 

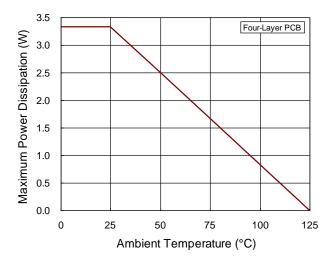

where  $T_{J(MAX)}$  is the maximum junction temperature,

TA is the ambient temperature, and  $\theta_{JA}$  is the junction-to-ambient thermal resistance.

For continuous operation, the maximum operating junction temperature indicated under Recommended 125°C. Operating Conditions is The junction-to-ambient thermal resistance, 0JA, is highly package dependent. For a WQFN-16L 3x3 package, the thermal resistance,  $\theta_{JA}$ , is 30°C/W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. The maximum power dissipation at TA = 25°C can be calculated as below :

 $\mathsf{P}\mathsf{D}(\mathsf{MAX})$  = (125°C - 25°C) / (30°C/W) = 3.33W for a WQFN-16L 3x3 package.

The maximum power dissipation depends on the operating ambient temperature for the fixed  $T_{J(MAX)}$  and the thermal resistance,  $\theta_{JA}$ . The derating curves in Figure 3 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

### Layout Considerations

For the best performance of the RT4720AC, the following PCB layout guidelines should be strictly followed.

For good regulation, place the power components as close to the IC as possible. The traces should be wide and short, especially for the high current output loop.

- The input and output bypass capacitor should be placed as close to the IC as possible and connected to the ground plane of the PCB.
- Minimize the size of the LX1, LX2, LX3 nodes and keep the traces wide and short. Care should be taken to avoid running traces that carry any noise-sensitive signals near LX or high-current traces.
- Separate power ground (PGND) and analog ground (AGND). Connect the AGND and the PGND islands at a single end. Make sure that there are no other connections between these separate ground planes.
- Connect the exposed pad to a strong ground plane for maximum thermal dissipation.
